CUDDALORE – 1.

Sandmeyer Reaction:-Definition:-

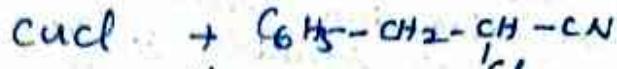

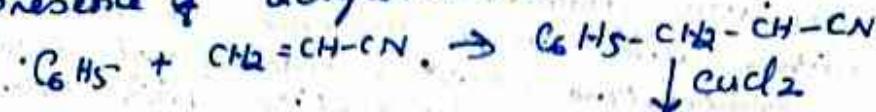

Conversion of an aromatic primary amine into an aryl diazonium salt by treatment with nitrous acid in the presence of mineral acids at low temperature (conoc). Subsequent decomposition of the diazonium salt by heating with cuprochloride or bromide in the presence of HCl chloride or bromide gives acyl chloride / corresponding halogen and gives acyl chloride / bromide.

Reaction:-Mechanism:-Step I:- formation of electrophilic reagent:-Step II:- formation of diazonium ion:-Step III:- formation of aryl radical:-

Cuprous copper has the power to reduce diazonium ion to aryl radical by oxidation-reduction involving one e- transfer.

PROOF FOR THE FORMATION OF ARYL RADICAL:-

Through free radical addition,
2-chloro-3-phenylpropionitrile is got by the
decomposition of benzene diazonium chloride in
the presence of acrylonitrile

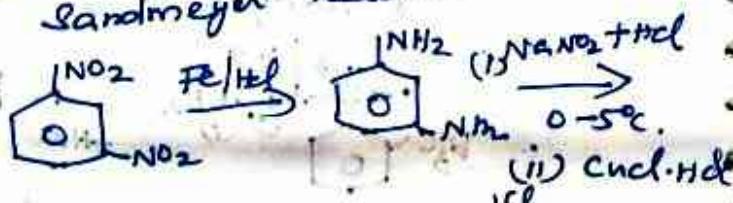

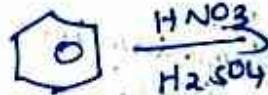

For the preparation of aryl iodide, the aryl diazonium salt is treated with KI solution. The cuprous catalyst is unnecessary, because iodide is sufficient to decompose the diazonium salt.

APPLICATIONS:-

1) Direct halogenation of aromatic compounds gives a mixture of isomers and difficult to separate. On the other hand, the diazonium salts give only one halogen derivative since the halogen enters at the position previously occupied by diazonium group.

2) Aryl iodides and fluorides which are never prepared by direct halogenation can be prepared by Sandmeyer reaction.

3) Direct halogenation at a particular position is not possible for reasons of electronic factors but this has been possible through Sandmeyer reaction.

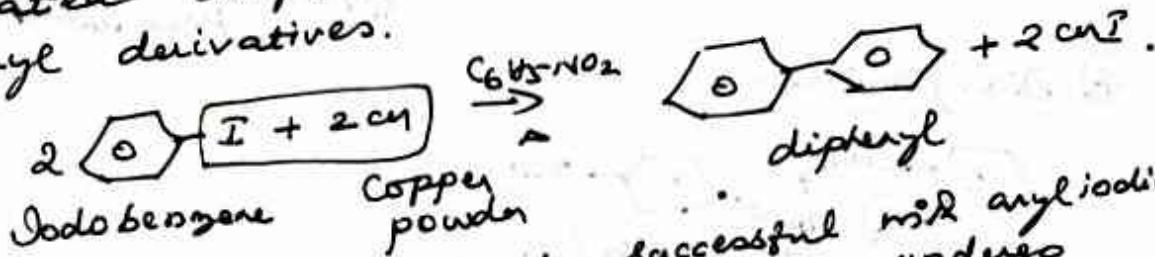

m-dichloro benzene

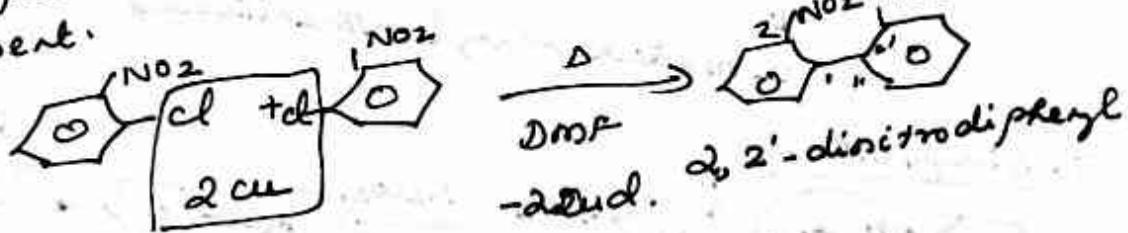

ULLMANN REACTION:-

Definition:-

Condensation of arylhalides in the presence of finely divided copper or copper bronze at an elevated temperature ($100-350^\circ\text{C}$) to yield diaryl derivatives.

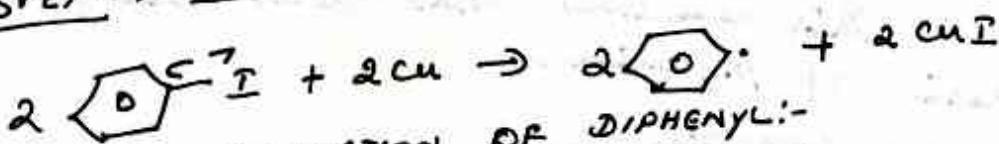

The reaction is successful with aryl iodides. Aryl bromides & aryl chlorides also undergo this reaction when electronegative substituents are present which activate the halogens are present.

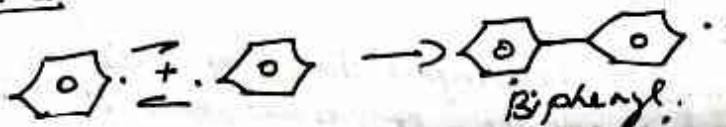

Mechanism:-

STEP I :- FORMATION OF PHENYL RADICAL:-

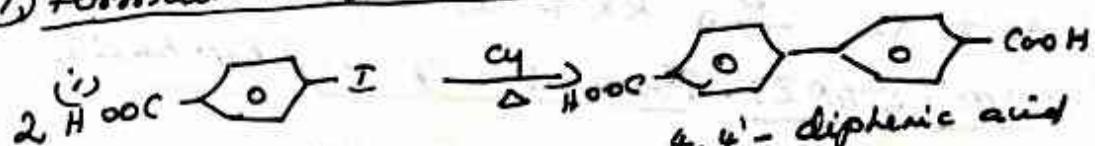

STEP II :- FORMATION OF DIPHENYL:-

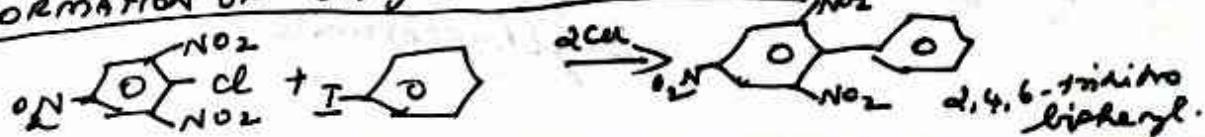

APPLICATIONS:-

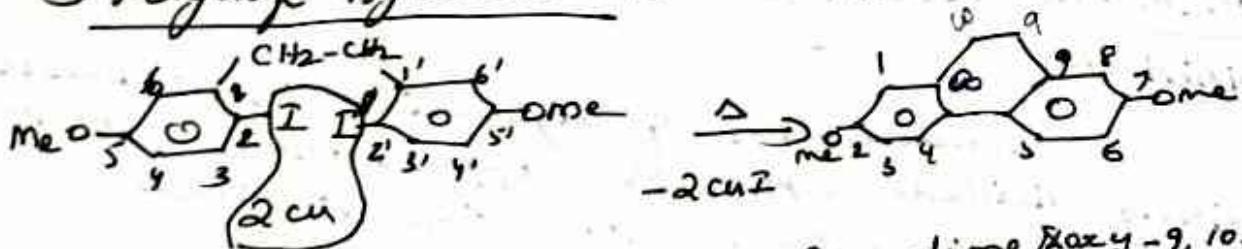

① FORMATION OF SYMMETRICAL BIARYLS:-

② FORMATION OF UNSYMMETRICAL BIARYLS:-

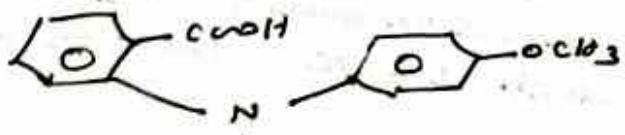

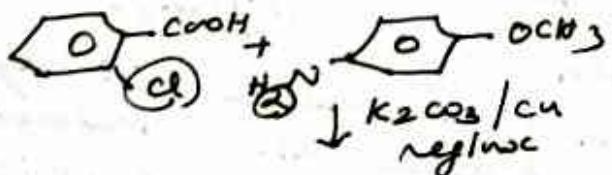

③ Polyenyl hydrocarbons:-

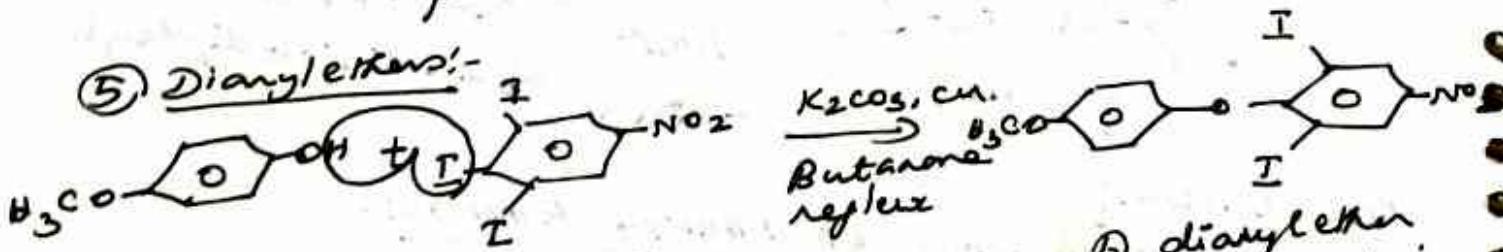

2,7-dimethoxy-9,10-dihydrophenanthrene.

④ Diarylamines:-

p-methoxyphenylbenzylamine.

⑤ Diarylethers:-

D. diarylether

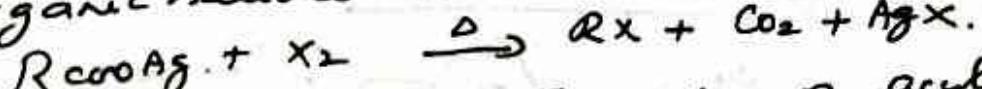

This reaction has been employed in

the synthesis of thyroxine.

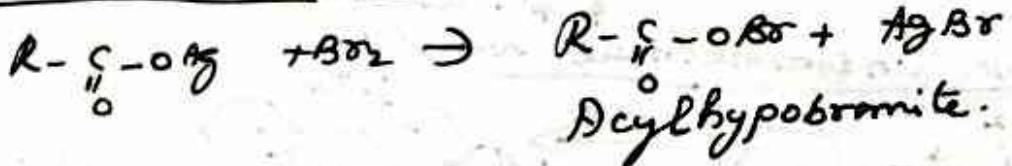

HUNSDIECKER REACTION:-

Definition:-

Thermal decomposition of silver salt of carboxylic acids in presence of halogens to give organic halides is known as Hunsdiecker reaction.

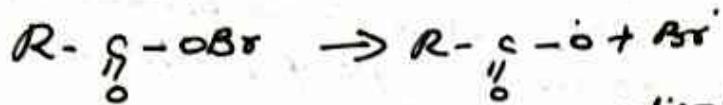

Mechanism:- STEP I:- Formation of acyl hypohalite-

③

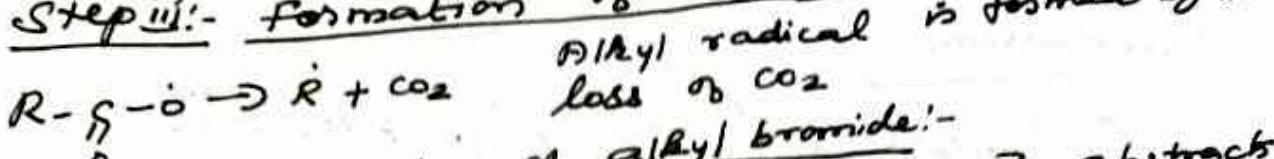

Step II :- Formation of α -cycloxy radical:-

α -cycloxy radical

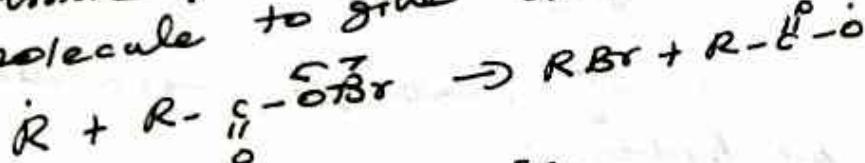

α -cycloxy radical

Step III :- Formation of alkyl radical:-

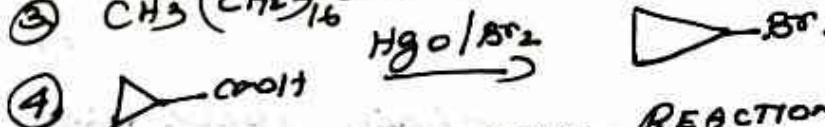

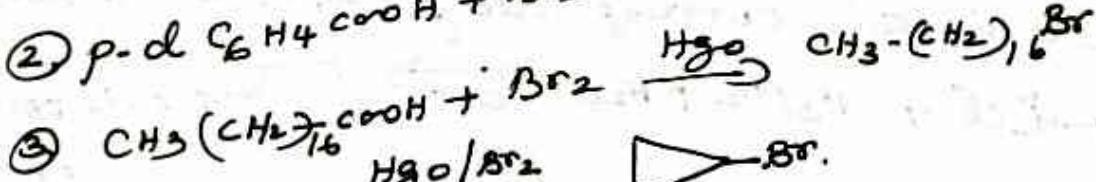

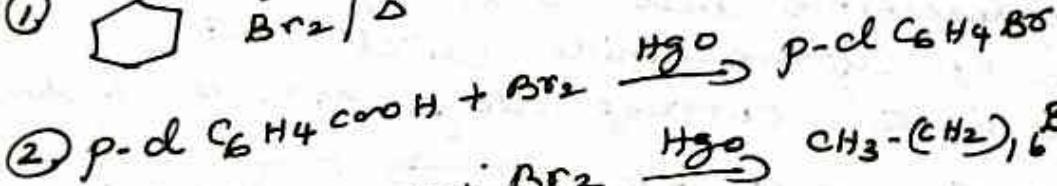

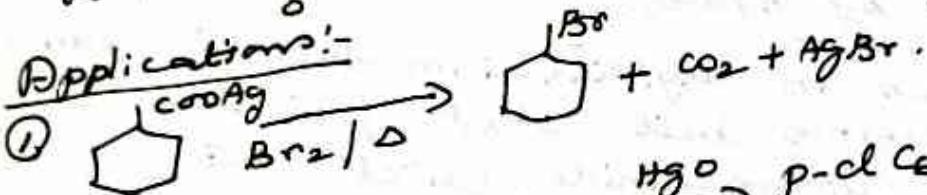

Step IV :- Formation of alkyl bromide:-

Alkyl radical formed in Step III abstracts bromine from the second Acyl Hypobromite molecule to give alkyl bromide.

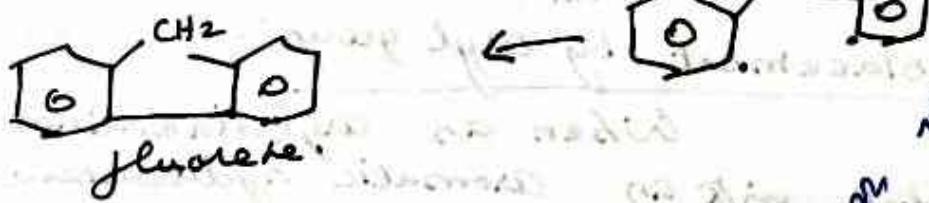

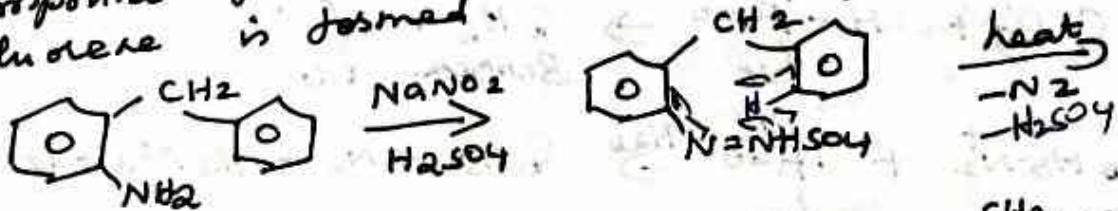

Applications:-

Pischot-Ring Closure REACTION:-

This is radical substitution reaction.
O-amino no diphenylmethane is converted into a 3D compound followed by the elimination of N_2 and fluorine is formed.

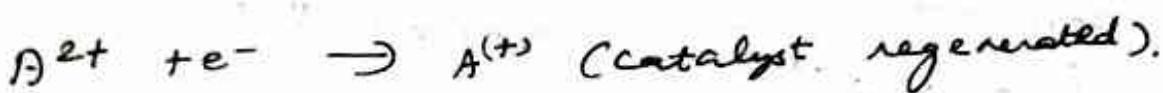

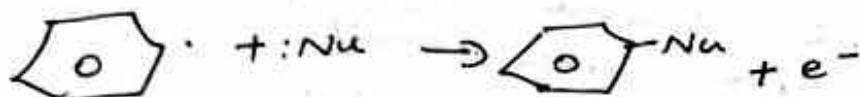

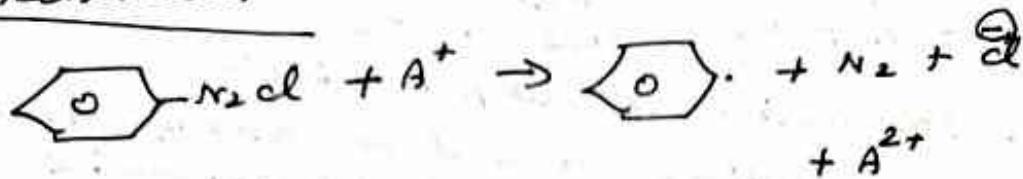

119
120
1216
1220
1222

Decomposition of diazo compounds -

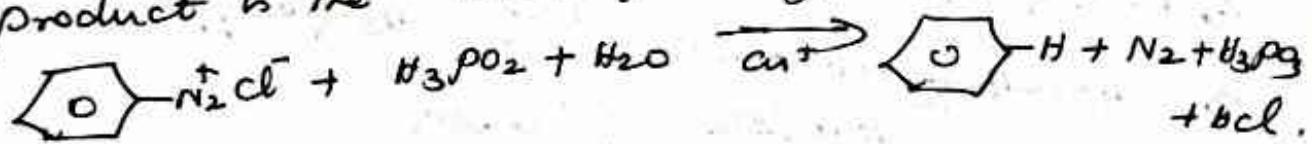

In Aryl diazonium salts, N_2X is replaced by another univalent atoms or group, with the liberation of N_2 gas.

Mechanism:-

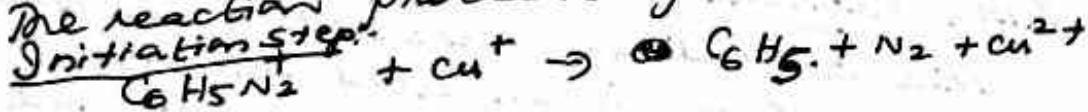

Replacement by hydrogen:-

When an aryl diazonium salt is reduced by Hypophosphorous acid (H_3PO_2) in the presence of Cuprous chloride ($Cu + Cl^-$) the product is the corresponding aromatic hydrocarbon.

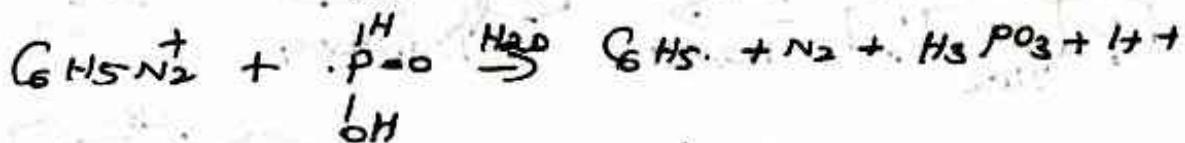

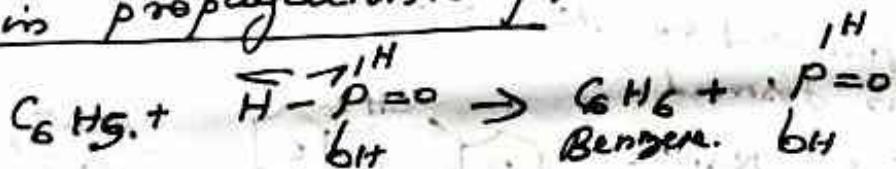

Mechanism:-

The reaction proceeds by \approx chain mechanism.

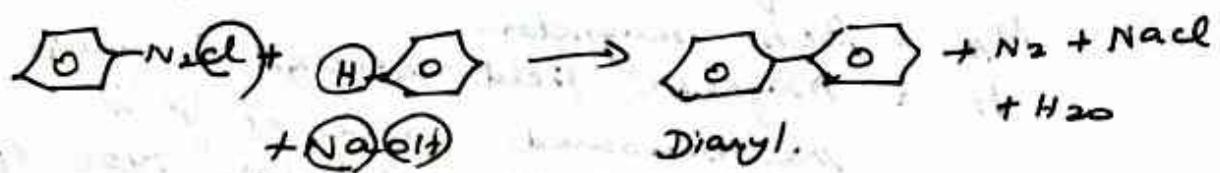

Chain propagation step:-

Replacement by aryl group:-

When an aryl diazonium chloride is treated with an aromatic hydrocarbon, the

in the presence of NaOH, diaryl results.

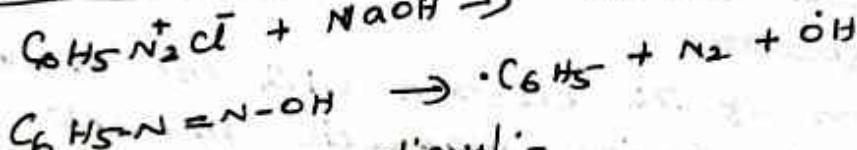

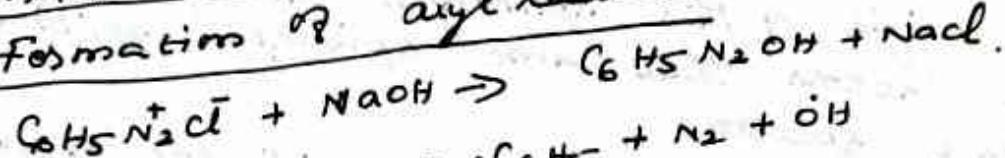

Mechanism:-

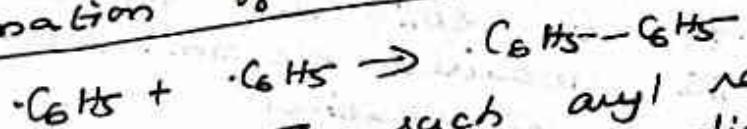

The reaction is believed to occur by a free-radical mechanism.

Chain initiation step:-

Formation of aryl radical:-

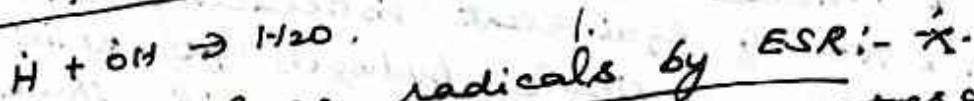

Formation of diaryl:-

Two such aryl radicals combine and there is formation of diaryl.

Chain termination step:-

Detection of free radicals by ESR:-

① Electron spin resonance spectroscopy is a highly specific tool for detecting radical species because only molecules with unpaired electrons give rise to ESR spectra.

② One feature that is determined in the ESR spectrum, which specifies the separation of the two spin states as a function of the magnetic field strength of the spectrometer.

$$③ \quad h\gamma = E - g \mu_B H$$

μ_B : Bohr magneton

H = magnetic field strength in gauss

The measured value of g' is the characteristic of the particular type of radical just as the line position in NMR spectra is characteristic of the absorbing nucleus.

④ More detailed structural information can be deduced from the hyperfine splitting in ESR spectra. The origin of this splitting is closely related to the factors that cause spin-spin splitting in 1H -NMR spectra.

⑤ Interaction of the electrons with one or more of the nuclei having magnetic moment like 1H , ^{13}C , ^{14}N etc splits the signal arising from the unpaired electrons. The no. of lines is given by the equation

$$= (2nI+1)$$

I = Nuclear spin quantum number

n = No. of equivalent interacting nuclei

⑥ If $I = 1/2$, a single hydrogen (H) splits a signal into a doublet. Interaction with three equivalent hydrogens as in a methyl group, gives splitting into four lines.

⑦ ^{12}C and ^{16}O has no nuclear magnetic moment

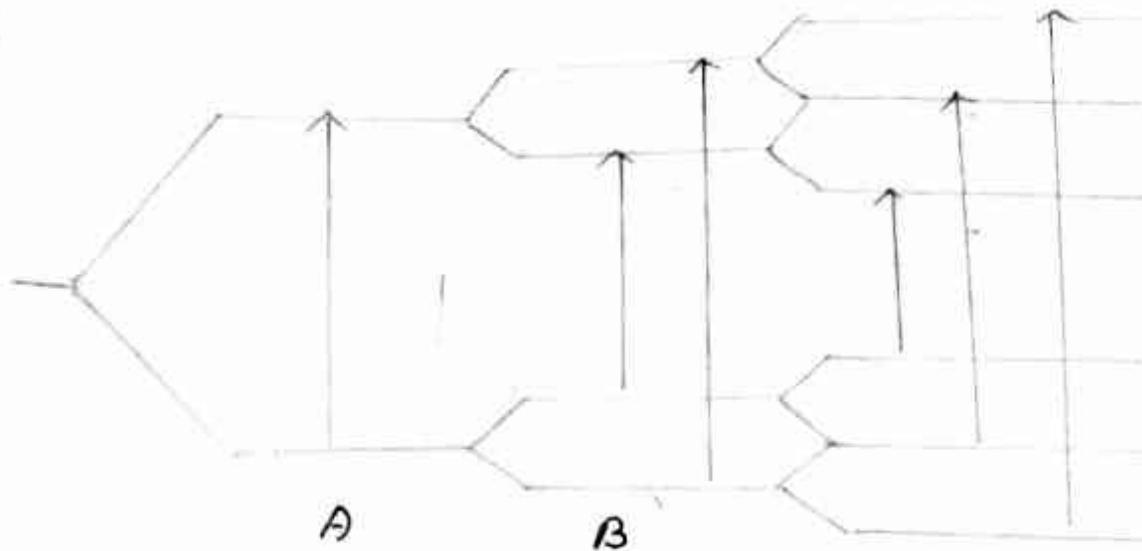

and they causes no signal splitting in ESR spectra.

⑧ The no. of lines indicates the number of interacting hydrogens if we limit our discussion for the moment of radicals without heteroatoms.

⑨ The magnitude of the splitting, given by hyperfine splitting constant a is a measure of the unpaired electron density in the hydrogen 1s orbital.

(5)

③

Hyperfine splitting in ESR

- A - No interacting nuclei. One absorption line.
- B - One interacting hydrogen. two absorption lines.
- C - Two interacting hydrogens. Three absorption lines.

④ For planar conjugated systems in which the unpaired electrons resides in a π -orbital system, the relationship between electron spin density and the splitting constant is given by McConnell equation

$$\alpha = P\varrho.$$

α = Hyperfine coupling constant for a proton.

ϱ = proportionality constant

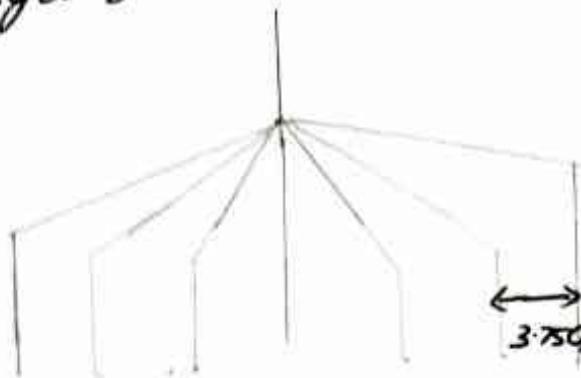

P = spin density on the carbon to which the hydrogen is attached.

⑤ $\varrho = 23.06$, the hyperfine splitting in the benzene radical anion can be readily calculated by taking $P = \frac{1}{6}$, because the one unpaired electron must be distributed equally among 6 C^6 atoms. The calculated value of $\alpha = 3.83$ is in good agreement with the observed value.

ESR spectra of radical anion

- (14) ESR spectra of free radicals can be studies even in very low concentration.
- (15) ESR spectrum of $C_6H_5^-$ has seven equally spaced lines which show that all six hydrogens are equivalent.

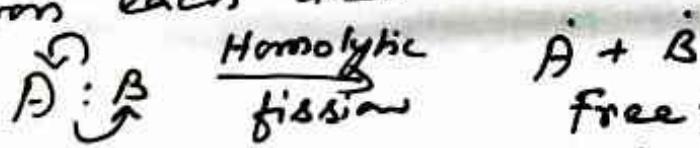

ESR spectrum of $C_6H_5^-$ showing the hyperfine splitting though equal coupling with six protons

- (16) The unpaired electron is coupling equally with all six hydrogens, rather than localised at one particular position. Since ^{12}C is nonmagnetic no further hyperfine splitting is produced.

FREE RADICALS:-

Definition:-

When a covalent bond undergoes homolytic fission, the two departing atoms take one electron of the bonding pair of electrons. The two fragments produced carry an odd electron each and are called free radicals.

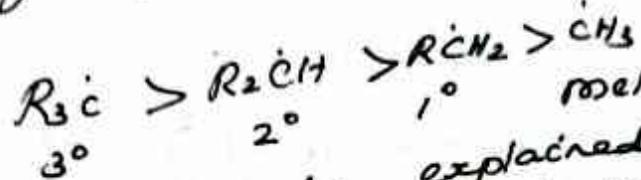

The term free radical is used for any species which possess an unpaired electron. The high reactivity of free radicals is due to the tendency of the odd electrons to pair up with another available electron.

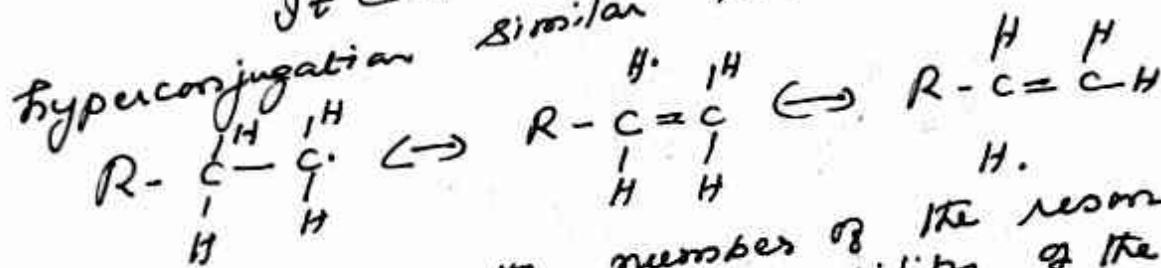

Stability of free radicals:-

SHORT & LONG LIVED FREE RADICALS:-

① Simple alkyl free radicals are highly reactive like carbocations and carbanions. Their lifetime is extremely short in solution. The relative stability of simple alkyl radicals has the order:

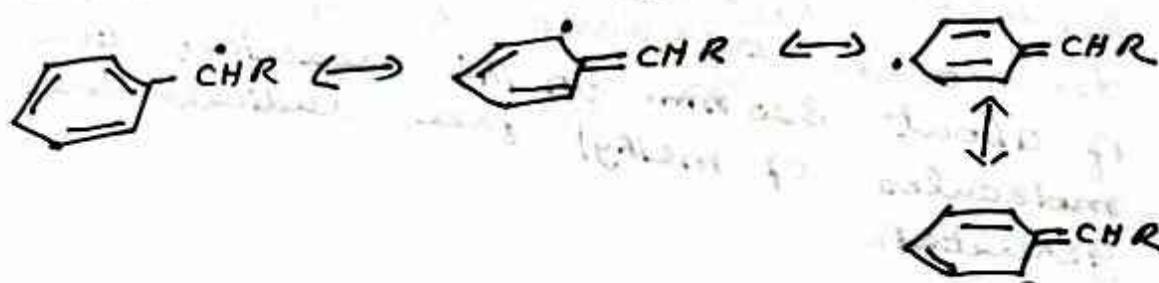

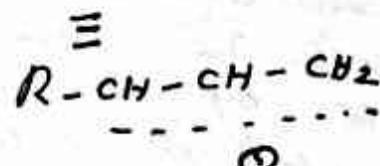

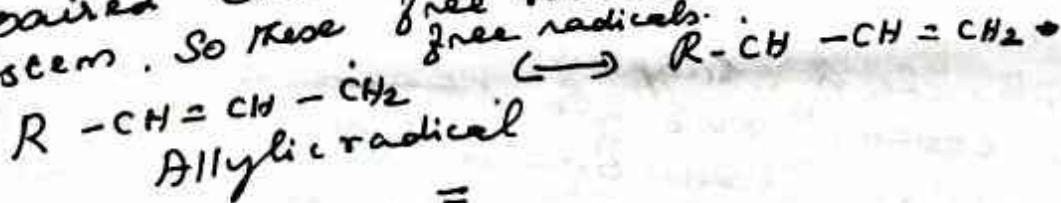

It can be explained on the basis of hyperconjugation similar to that in carbocation.

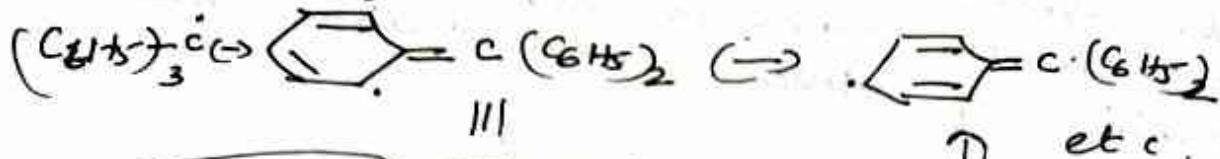

More the number of the resonance structures, greater is the stability of the free radical.

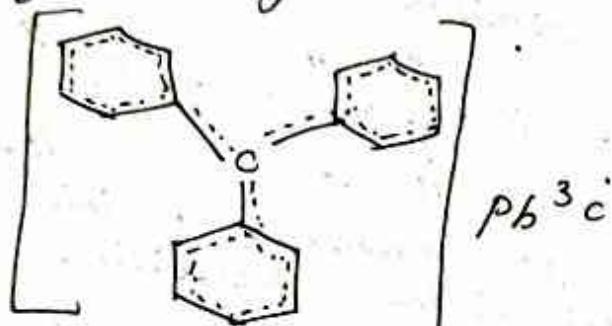

② Allylic and benzylic free radicals are more stable and comparatively less reactive than simple alkyl radicals. The reason is the delocalisation of the unpaired electron over the π -orbital system. So these free radicals are long lived.

③ Triphenyl methyl and trianglyloethyl radicals are much more stable in solution at room temperature. The stability of such radicals is due to resonance. They are also long lived free radicals.

Steric hindrance to dimerisation is probably the major cause of their stability.

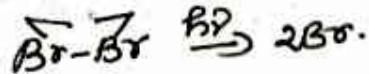

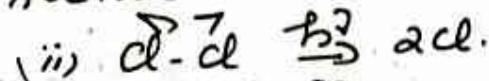

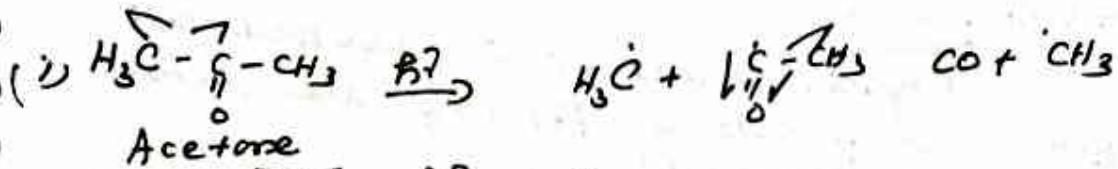

Generation of free radicals:-

Homolytic cleavage of a double bond generates a pair of free radicals.

① Photolysis:-

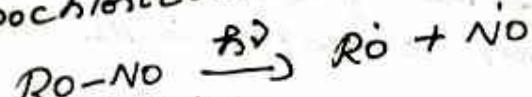

In this method, a suitable organic molecule is subjected to UV radiation. The organic molecule should be able to absorb radiation in the ultraviolet or visible range. The cleavage of a molecule into two parts by using UV light is known as photolysis. Acetone in vapour phase is decomposed by light having a wavelength of about 320 nm. In this reaction, two molecules of methyl free radicals are generated.

(7)

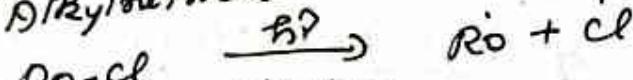

These free radicals (Br & Cl)
can initiate the halogenation of alkanes or
addition to alkenes.

(iii) Alkoxyl free radicals are generated
by photolysis of alkyl nitrites and alkyl
hypochlorites.

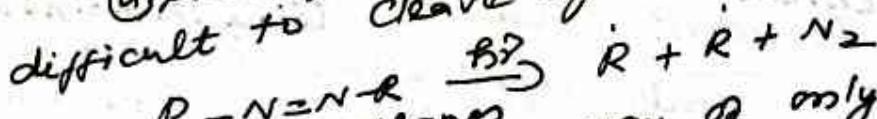

Alkyl nitrites

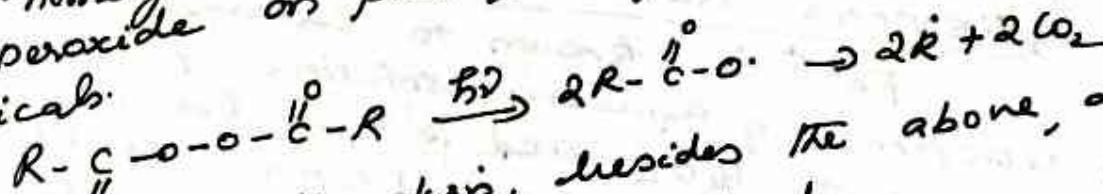

Alkyl hypochlorites

Method has two basic
advantages over the thermolysis for the generation
of free radicals

① photolysis cleave strong bonds that are
difficult to cleave by thermolysis.

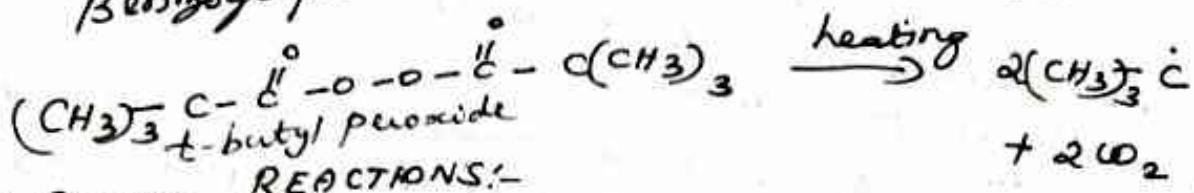

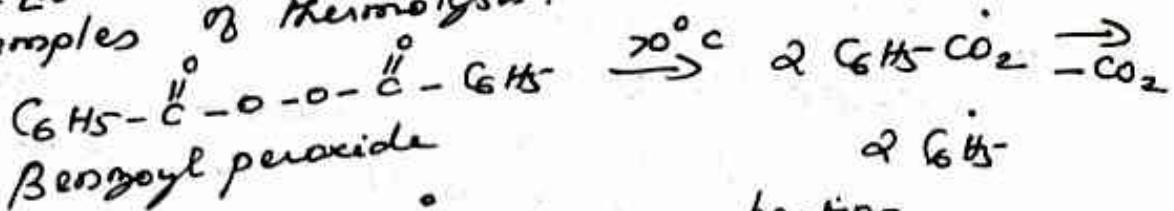

② In photolysis, energy of only one particular
wavelength is transferred to a molecule and
in this way photolysis is a specific method
for homolytic cleavage than pyrolysis. Thus
acylperoxide on photolysis generates the free
radicals.

In thermolysis, besides the above, a
no of other byproducts are obtained.

II THERMOLYSIS:-

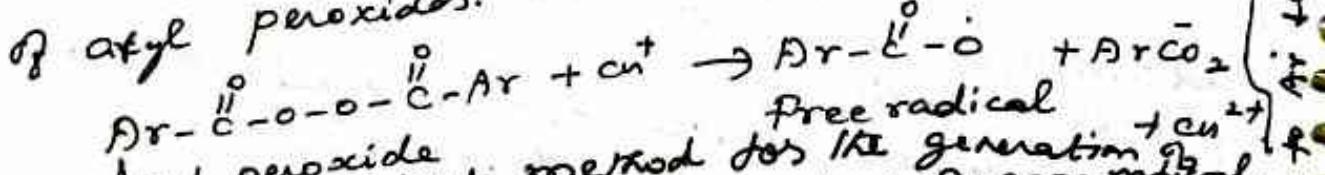

Organic substrate is heated at suitable temperature. Following are some examples of thermolysis.

III REDOX REACTIONS:-

In redox reactions, there is one electron transfer in generating the free radicals. The source of one electrons transfer is the metal ion (eg) Cu^{2+} , Fe^{2+} etc.

(a) Decomposition of aryl peroxides: (Reduction)
Cu⁺ ions are used for the decomposition of aryl peroxides.

This is a convenient method for the generation of ArCOO^- radical since thermolysis leads

(b) Sandmeyer Reaction: (Reduction) Cu²⁺ also finds application in Sandmeyer reaction, involving decomposition of diazonium salts. In this reaction, the free radical Ar is formed as an intermediate. Ar-N₂ → CuCl₂ + N₂ + Ar

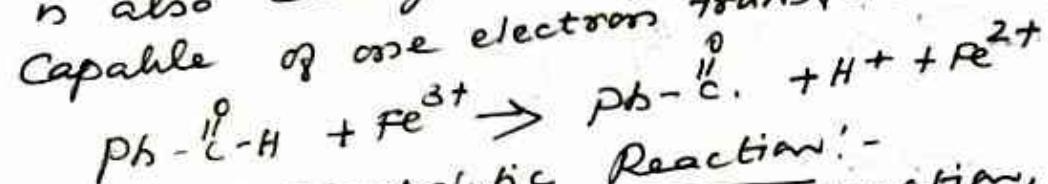

(c) FENTON'S REACTION: (Coxidation) Fe²⁺ is known to catalyse the oxidation

reactions of aqueous solution of H₂O₂. The mixture of H₂O₂ and Fe²⁺ is known as Fenton's reagent. The effective oxidising agent is the hydroxyl radical HO[·] and the reaction is known as Fenton's reaction.

$\text{HCH}_2 - \text{C}(\text{me}) - \text{OH} + \text{OH}^- \rightarrow \text{HO} + \text{OH}_2\text{C}(\text{me})_2\text{OH}$ (free radical)

Carbonyl me me
 $\text{H}_2\text{O}_2 + \text{Fe}^{2+} \rightarrow \text{Fe}^{3+} + \text{H}\dot{\text{O}} + \text{OH}^-$. The formed OH Radical is used to produce another free radical when suitable substrate reacts with it.

(d) Autoxidation:- C_2^+ reacts with suitable substrate as follows & The autoxidation of benzaldehyde is also catalysed by metal ions which are capable of one electrons transfer.

(e) Kolbe Electrolytic Reaction:-
 In Kolbe's electrolytic reaction, free radicals are the intermediate as follows.
 $2\text{RCO}_2^- \xrightarrow[\text{anode}]{-\text{e}^-} 2\text{RCO}_2 \xrightarrow{-\text{CO}_2} 2\text{R} \rightarrow \text{R}-\text{R}$.

Addition reactions:-
Addition reactions to carbon-carbon double bond:-

- (i) Addition to halogens
- (ii) Addition to halogen acids.
- (iii) Polymerisation reactions.

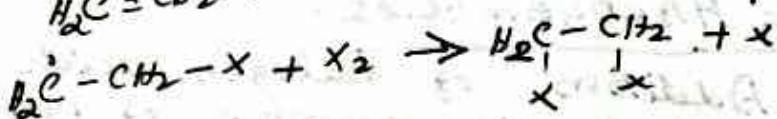

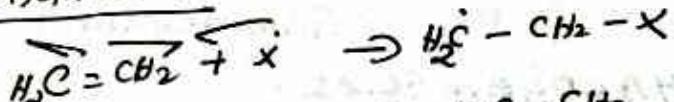

Addition to halogens:-

Addition of halogens in non-polar solvents in gas phase or by light takes through radical intermediate.

INITIATION:- $\text{X-X} \xrightarrow{\text{heat/light}} \text{X} + \text{X}$

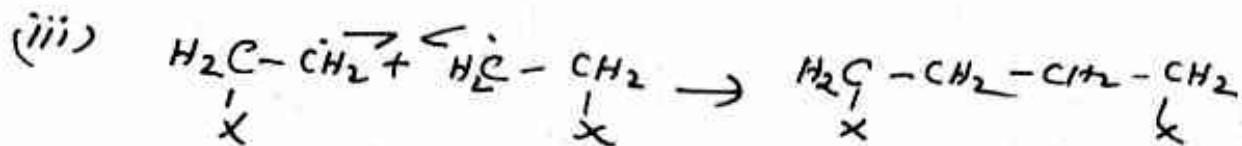

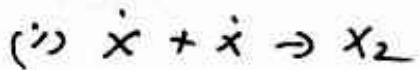

1. Halogen

PROPAGATION:-

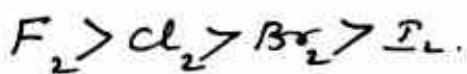

TERMINATION:-

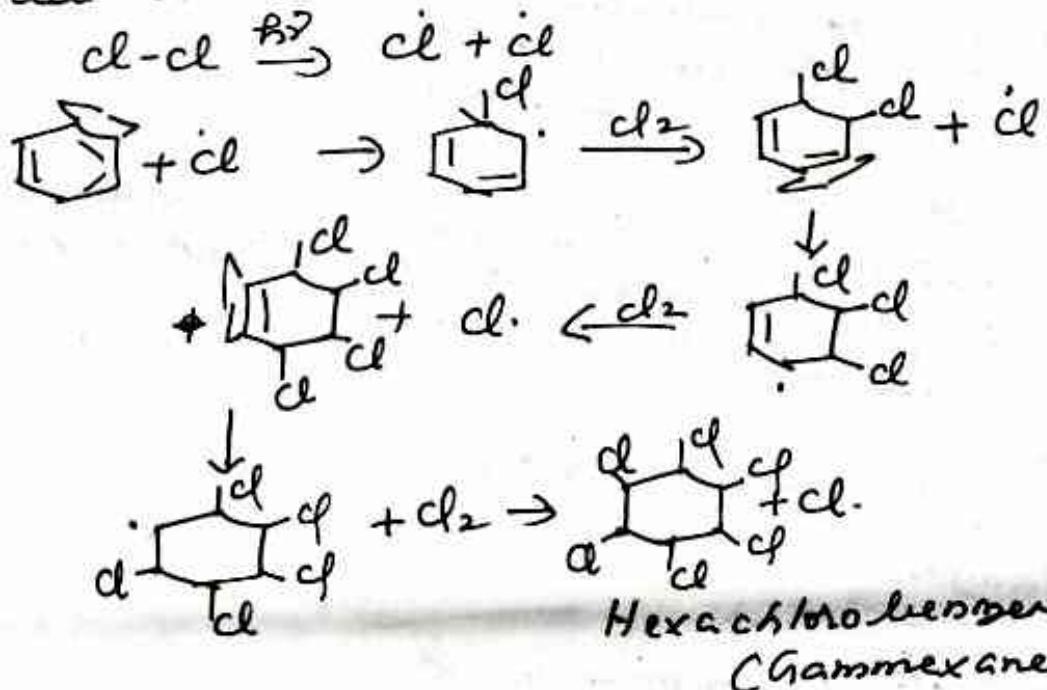

There are 3 ways to terminate the reaction

The order of reactivity of halogens

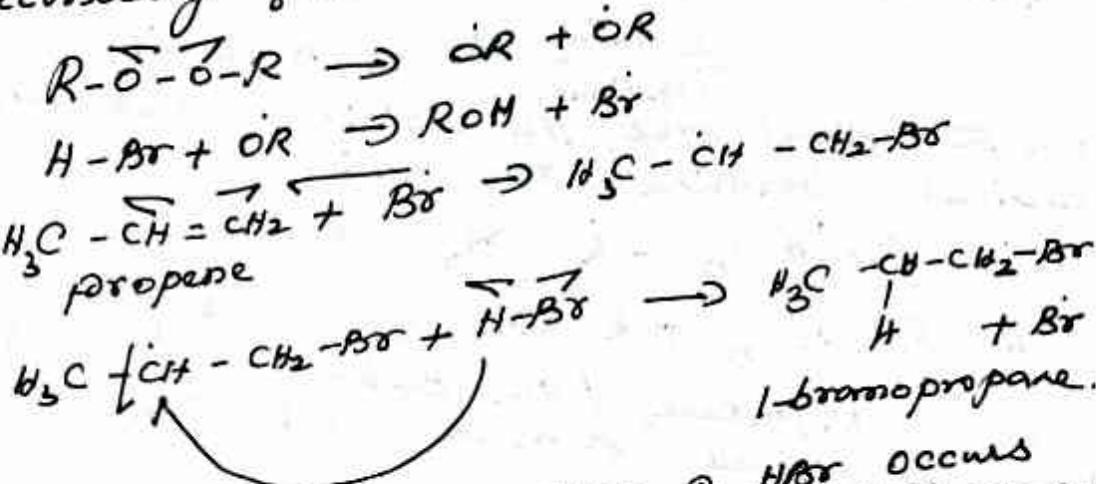

Addition of halogen particularly chlorine to benzene is also an example of radical addition.

II ADDITION OF HALOGEN ACIDS:-

① Addition of halogen acids to unsymmetrical alkene in presence of peroxides

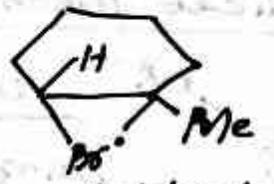

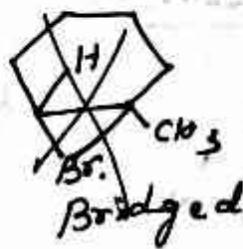

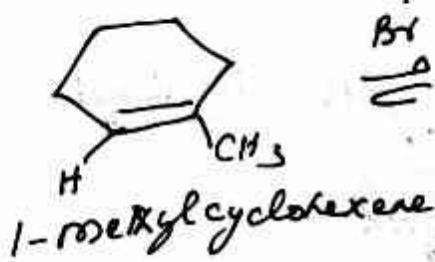

proceeds through radical intermediate giving Anti-Markownikov addition. This is generally referred as peroxide effect. In this reaction, halogen radical attacks unsymmetrical halogen radical attacks unsymmetrical alkenes to generate a more stable secondary free radical.

Only the addition of HBr occurs with peroxide effect but other halogen acids undergo addition according to Markownikov's rule. This is due to the fact that addition of HBr is an exothermic process while addition of other halogen acids takes place through endothermic step.

SUBSTITUTED CYCLOHEXENES:-

(b) ADDITION TO SUBSTITUTED CYCLOHEXENES: Radical addition of HBr is to and ~~anti~~, anti addition.

1/2 Antiaddition of
 HBr

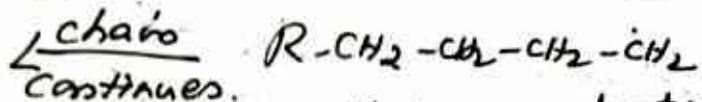

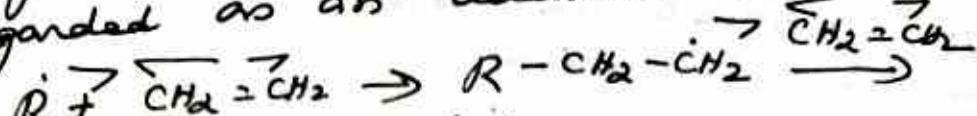

(Anti addition)

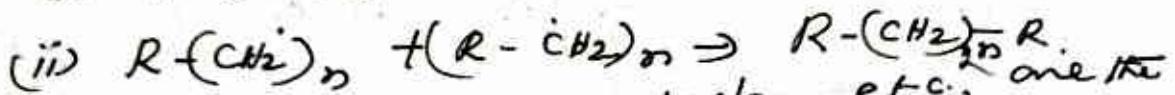

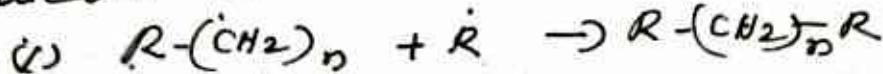

Cis-1-bromo-2-methylcyclohexane

III Polymerisation:-

Radical reactions can produce polymers of great importance. Polymerisation may be regarded as an addition reaction. Thus

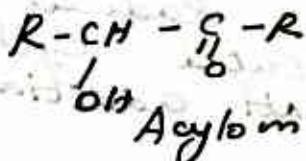

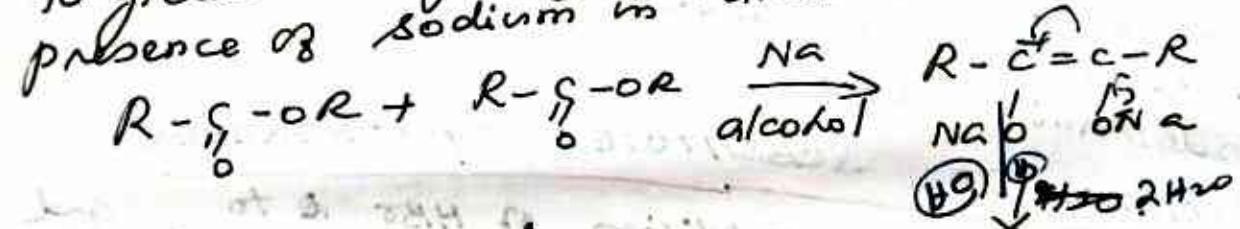

In the final step, the collisions between radicals terminate the chain.

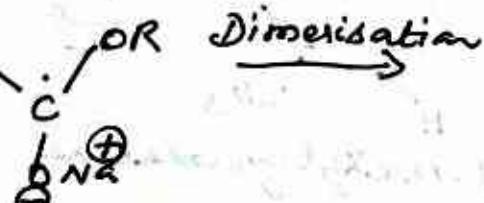

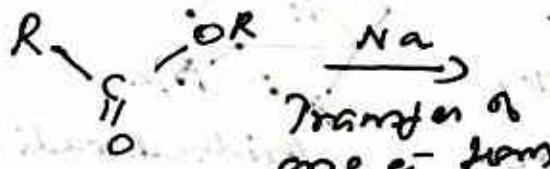

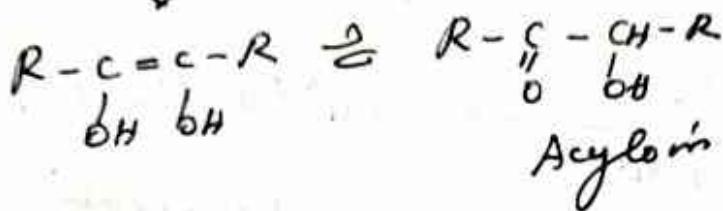

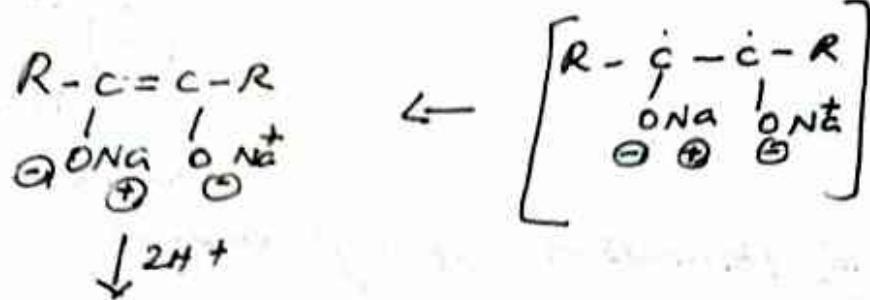

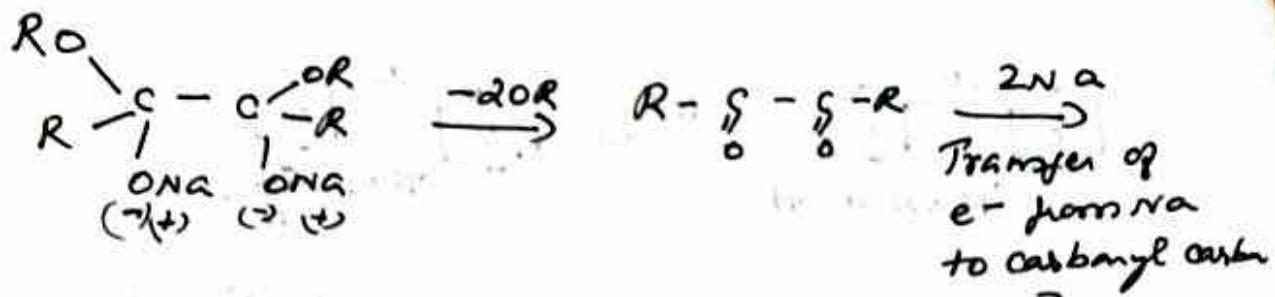

Polykene, PVC, teflon etc., are the polymers formed from the respective monomers by radical pathway.

Acylomis condensation may be regarded as an example of radical addition reaction. It is a case of dimerisation of ester to yield α -hydroxy ketone (Acylomis) in presence of sodium in alcohol.

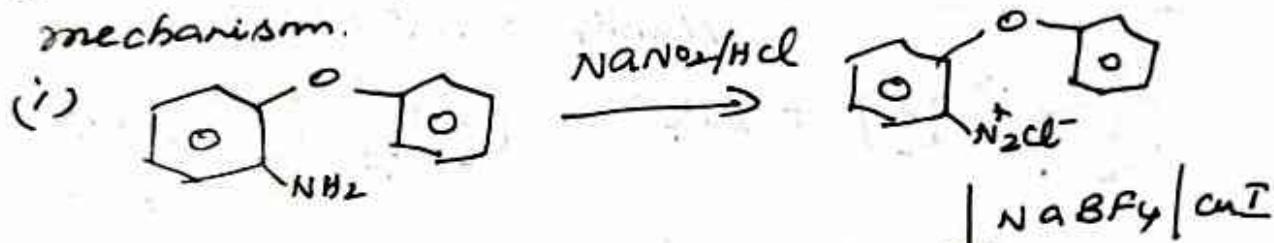

Radical Mechanism:-

① Predict the products and suggest suitable mechanism.

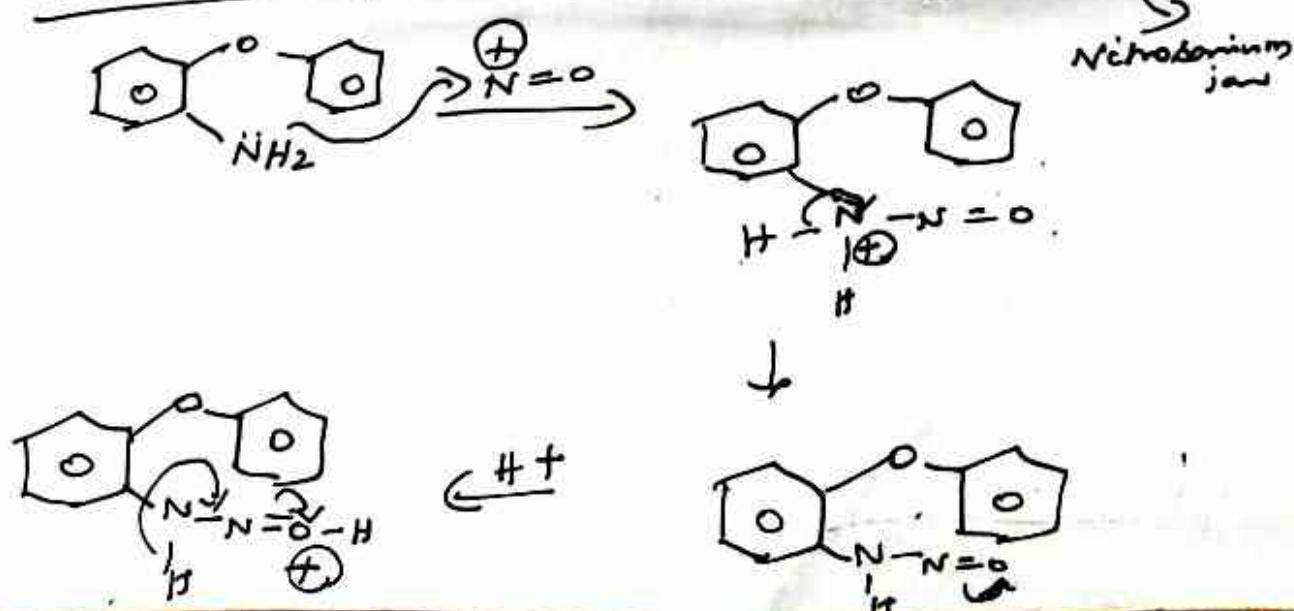

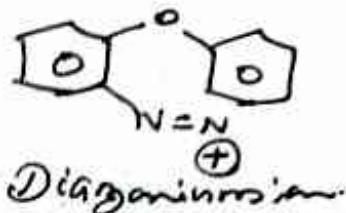

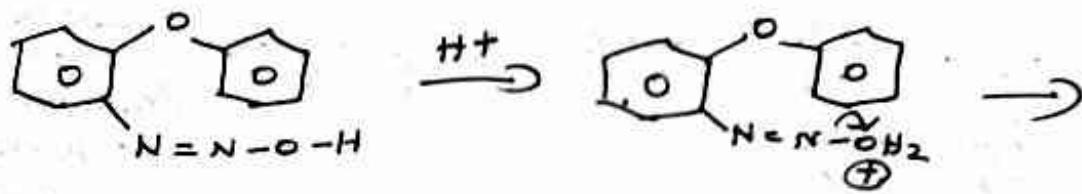

Mechanism:-

Step I: Formation of nitroso ion
 $\text{NaNO}_2 + \text{HCl} \rightarrow \text{HOONO} + \text{NaCl}$

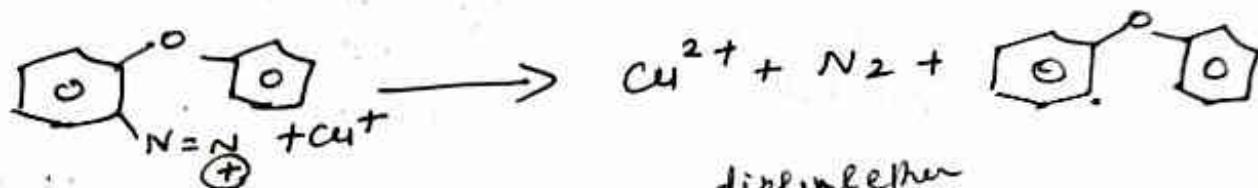

Step II:
 $\text{HOONO} + \text{H}^+ \rightarrow \text{H}_2\text{NO}^+ + \text{H}_2\text{O}$

Formation of diazonium ion:-

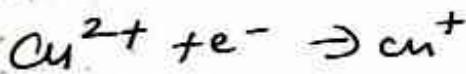

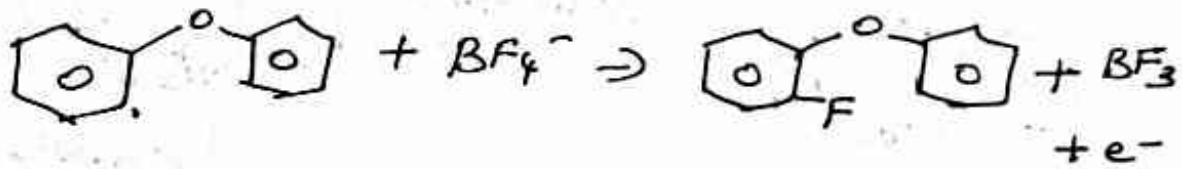

Step III formation of aryl radical:-

Step IV formation of O-fluorobenzene:-

+ H
